

高可用性、负载均衡的 mysql 集群解决方案

- 一、mysql 的市场占有率
- 二、mysql 为什么受到如此的欢迎
- 三、mysql 数据库系统的优缺点
- 四、网络服务器的需求
- 五、什么是 mysql 的集群
- 六、什么是负载均衡
- 七、mysql 集群部署和实现方法
- 八、负载均衡的配置和测试
- 九、Mysql 集群系统的测试（测试方案+测试脚本+测试结果分析）
- mysql 的市场占有率

MySQL 是世界上最流行的开源数据库，已有1100多万的激活安装，每天超过五万的下载。MySQL 为全球开发者、DBA 和 IT 管理者在可靠性、性能、易用性方面提供了选择。

第三方市场调查机构 Evans Data Corporation 调查显示，过去两年内在开发者使用的所有数据库中，MySQL 已经拥有了25%的市场占有率。开源已经成为当今 IT 结构中不可或缺的重要部分，而且开源的市场占有率将继续增加。如下图所示：

- mysql 为什么受到如此的欢迎

Sun 公司今天1月份花了10亿美元将 mysql 收购，准备进军开源和数据库。

数据库系统	Oracle	SQL Server	MySQL	DB2
是否免费	收费	收费	免费	收费
存储过程	支持	支持	支持	支持
视图	支持	支持	支持	支持
快照	支持	支持	不支持	支持
触发器	支持	支持	支持	支持
安全	强	中	中	强
复杂查询	强	中	弱	中

索引	丰富	一般	弱	中
数据类型	多	多	多	多
事务处理	强	强	弱	中

● mysql 数据库系统的优缺点

每个系统都有自身的不足和发展历程，mysql 也一样。

优点

1. 源码公开，免费
2. 跨平台
3. 为多种开发语言和包提供了 API
4. 支持多线程
5. 小巧、灵活、速度较快
6. 支持各种字符集
7. 提供各种连接、优化的工具包

缺点

1. 不完善，很多数据库特性不支持
2. 只适合中小型应用，对于大型应用，可以跟其他数据库互补；
3. 数据库系统数据量只能达到千万级别；

● 网络服务的需求

随着 Internet 的飞速发展和对我们生活的深入影响，越来越多的个人在互联网上购物、娱乐、休闲、与人沟通、获取信息；越来越多的企业把他们与顾客和业务伙伴之间的联络搬到互联网上，通过网络来完成交易，建立与客户之间的联系。互联网的用户数和网络流量正以几何级数增长，这对网络服务的可伸缩性提出很高的要求。例如，比较热门的 Web 站点会因为被访问次数急剧增长而不能及时处理用户的请求，导致用户进行长时间的等待，大大降低了服务质量。另外，随着电子商务等关键性应用在网上运行，任何例外的服务中断都将造成不可估量的损失，服务的高可用性也越来越重要。所以，对用硬件和软件方法实现高可伸缩、高可用网络服务的需求不断增长，这种需求可以归结以下几点：

- 1) 可伸缩性 (Scalability)，当服务的负载增长时，系统能被扩展来满足需求，且不降低服务质量。
- 2) 高可用性 (Availability)，尽管部分硬件和软件会发生故障，整个系统的服务必须是每天24小时每星期7天可用的。
- 3) 可管理性 (Manageability)，整个系统可能在物理上很大，但应该容易管理。
- 4) 价格有效性 (Cost-effectiveness)，整个系统实现是经济的、易支付的。

单服务器显然不能处理不断增长的负载。这种服务器升级方法有下列不足：一是升级过程繁琐，机器切换会使服务暂时中断，并造成原有计算资源的浪费；二是越往高端的服务器，所花费的代价越大；三是一旦该服务器或应用软件失效，会导致整个服务的中断。

通过高性能网络或局域网互联的服务器集群正成为实现高可伸缩的、高可用网络服务的有效结构。这种松耦合结构比紧耦合的多处理器系统具有更好的伸缩性和性能价格比，组成

集群的 PC 服务器或 RISC 服务器和标准网络设备因为大规模生产，价格低，具有很高的性能价格比。但是，这里有很多挑战性的工作，如何在集群系统实现并行网络服务，它对外是透明的，它具有良好的可伸缩性和可用性。

针对上述需求，我们给出了基于 IP 层和基于内容请求分发的负载平衡调度解决方法，并在 Linux 内核中实现了这些方法，将一组服务器构成一个实现可伸缩的、高可用网络服务的服务器集群，我们称之为 Linux 虚拟服务器（Linux Virtual Server）。在 LVS 集群中，使得服务器集群的结构对客户是透明的，客户访问集群提供的网络服务就像访问一台高性能、高可用的服务器一样。客户程序不受服务器集群的影响不需作任何修改。系统的伸缩性通过在服务机群中透明地加入和删除一个节点来达到，通过检测节点或服务进程故障和正确地重置系统达到高可用性。

● 什么是 mysql 集群

分为同步集群和异步集群。

同步集群 (mysql cluster)

结构: (**data + sql + mgm** 节点)

特点:

- 1) 内存级别的，对硬件要求较低，但是对内存要求较大。换算比例为: 1: 1.1;
- 2) 数据同时放在几台服务器上，冗余较好；
- 3) 速度一般；
- 4) 建表需要声明为 engine=ndbcluster
- 5) 扩展性强；
- 6) 可以实现高可用性和负载均衡，实现对大型应用的支持；
- 7) 必须是特定的 mysql 版本，如：已经编译好的 max 版本；
- 8) 配置和管理方便，不会丢失数据；

异步集群 (mysql replication)

结构: (**master + slave**)

特点:

- 1) 主从数据库异步数据；
- 2) 数据放在几台服务器上，冗余一般；
- 3) 速度较快；
- 4) 扩展性差；
- 5) 无法实现高可用性和负载均衡(只能在程序级别实现读写分离，减轻对主数据库的压力)；
- 6) 配置和管理较差，可能会丢失数据；

● 什么是负载均衡

通过 director，将用户的请求分发到 real server 服务器上，然后返回给用户。

负载均衡部署灵活、能够满足各种需求。

实现方式:

硬件: BIG/IP、Cisco、IBM (昂贵)

软件: LVS (免费)

LVS 系统将用户的请求的数据包在数据层和网络层进行了封装和转发，由三种方式满足各种需求。

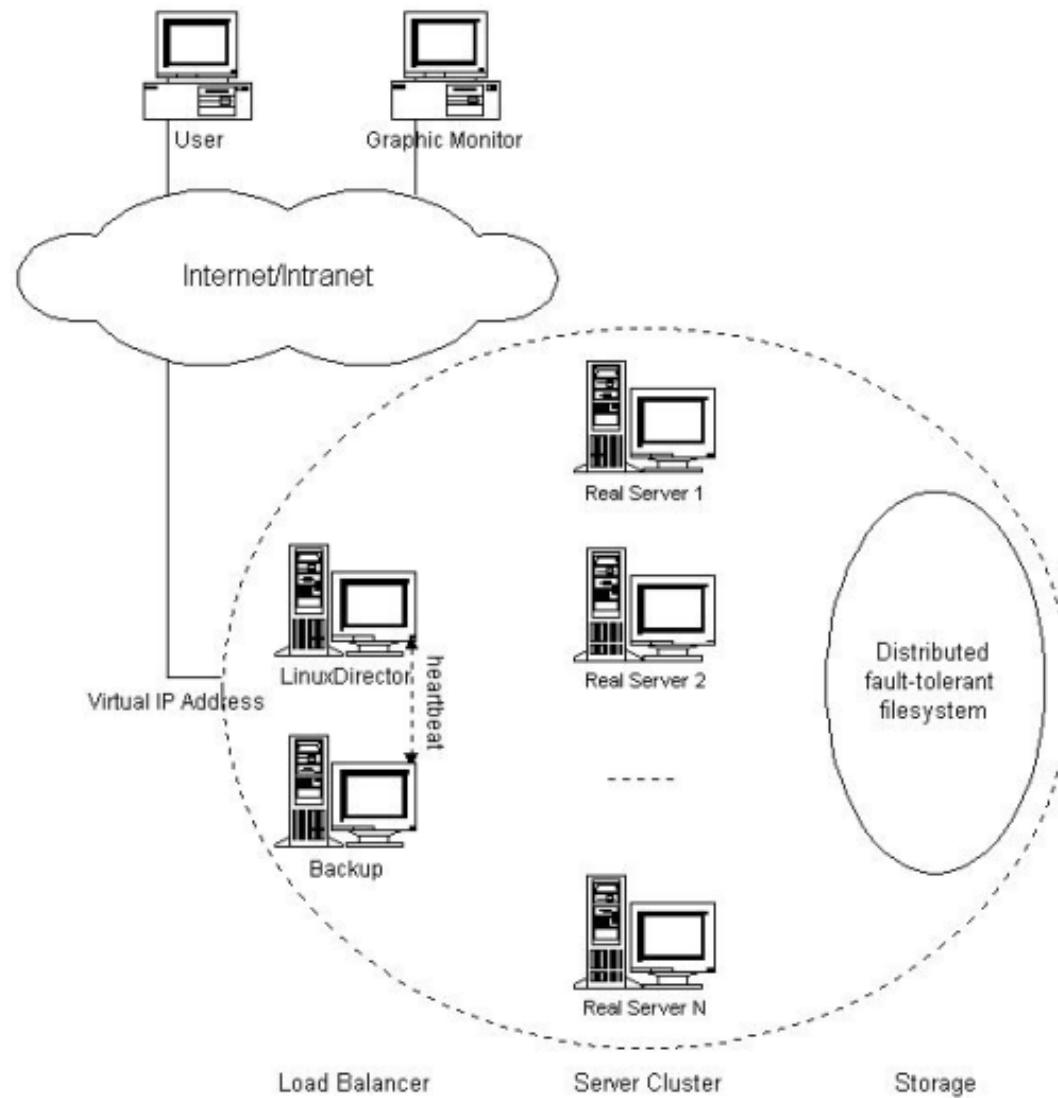

- 1) DR: 直接路由
- 2) Tuning: tcp/ip 隧道
- 3) NAT: 网络地址转换

需求:

免费的软件包

- 1) 2台低端的 director (active 和 standby)
- 2) 心跳线: 连接2台 director, 检测活动情况
- 3) 2台以上的 real servers

通用结构:

有兴趣的可以分别研究上面的三种 LVS 结构。

● mysql 集群部署和实现方法

1) 假设现在有4台服务器 (mysql 官方推荐的最小配置)

服务器	开启的服务	角色
192.168.131.16	Mysqld	Mysql API
4	Ndb_mgmd	管理节点(master)
Ndb1	Heartbeat	Director(master)
192.168.131.26	Mysqld	Mysql API
Ndb2	Ndb_mgmd	管理节点(backup)
	Heartbeat	Director(standby)
192.168.131.77	Mysqld	Mysql API (realserver)
Sq11	Nbdb	存储节点
	Arptables	访问路由
192.168.131.10	Mysqld	Mysql API (realserver)
1	Nbdb	存储节点
Sq12	Arptables	访问路由

2) 服务器安装配置和网络连接

(以下为所有服务器各操作一遍, 共4遍)

安装:

将4台服务器安装 CentOS 5.2, 选择下面的包:

Clustering

Storage Clustering

mysql 不需要安装, 但 perl-mysql-xxx 的所有包需要安装

开发工具包和类库

sshd 服务

SELinux ==> disable

语言支持包不安装, 默认美国英语

设定主机名:

Vi /etc/sysconfig/network

Hostname=xxx

:wq

检查主机名:

Uname -a

必须和上表中的一一对应。否则有问题。

Vi /etc/hosts

Ndb1 192.168.131.164
Ndb2 192.168.131.26
Sql1 192.168.131.77
Sql2 192.168.131.101

更新:

```
#rpm --import http://dries.ulyssis.org/rpm/RPM-GPG-KEY.dries.txt
#yum update -y && yum -y install lynx libawt xorg-x11-deprecated-libs nx freenx arptables_jf
httpd-devel
```

下载:

Mysql cluster 版本 (我下载的5.0.67社区版本):

```
[root@ndb1 RHEL5]# ls -lh MySQL* | awk '{print $9}'
MySQL-client-community-5.0.67-0.rhel5.i386.rpm
MySQL-clusterextra-community-5.0.67-0.rhel5.i386.rpm
MySQL-clustermanagement-community-5.0.67-0.rhel5.i386.rpm
MySQL-clusterstorage-community-5.0.67-0.rhel5.i386.rpm
MySQL-clustertools-community-5.0.67-0.rhel5.i386.rpm
MySQL-devel-community-5.0.67-0.rhel5.i386.rpm
MySQL-server-community-5.0.67-0.rhel5.i386.rpm
MySQL-shared-community-5.0.67-0.rhel5.i386.rpm
MySQL-shared-compat-5.0.67-0.rhel4.i386.rpm
MySQL-shared-compat-5.0.67-0.rhel5.i386.rpm
MySQL-test-community-5.0.67-0.rhel5.i386.rpm
perl-HTML-Template-2.9-1.el5.rf.noarch.rpm
[root@ndb1 RHEL5]#
```

在服务器上安装以上包，在安装的过程中如果缺少包或者库，采用:

yum install xxxx 自行安装。

建立目录:

```
#mkdir /var/lib/mysql-cluster -p
```

以下分别操作:

安装 cluster 组件:

```
#Rpm -Uvh MySQL-xx-xx.rpm, 根据不同, 可以少安装部分组件。根据你需要而定。
```

163、26上，我安装了:

```
[root@ndb1 RHEL5]# rpm -aq | grep MySQL
MySQL-clusterstorage-community-5.0.67-0.rhel5
MySQL-clustertools-community-5.0.67-0.rhel5
MySQL-clustermanagement-community-5.0.67-0.rhel5
```

```
MySQL-shared-community-5.0.67-0.rhel5
perl-DBD-MySQL-3.0007-1.fc6
MySQL-server-community-5.0.67-0.rhel5
[root@ndb1 RHEL5]#
```

101、77上，我安装了：

```
[root@sql1 ~]# rpm -aq | grep MySQL
MySQL-clusterstorage-community-5.0.67-0.rhel4
MySQL-devel-community-5.0.67-0.rhel4
MySQL-server-community-5.0.67-0.rhel4
MySQL-client-community-5.0.67-0.rhel4
MySQL-shared-community-5.0.67-0.rhel4
[root@sql1 ~]#
```

以下在 ndb1 (164) 和 ndb2 (26) 上操作

```
[root@ndb1 ~]# vi /var/lib/mysql-cluster/config.ini
[NDBD DEFAULT]
NoOfReplicas=2
DataMemory=800M
IndexMemory=400M

[mysqld DEFAULT]
```

```
[NDB_MGMD DEFAULT]
```

```
[TCP DEFAULT]

# Section for the cluster management node
[NDB_MGMD]
# IP address of the management node (this system)
ID=1
HostName=192.168.131.164
```

```
[NDB_MGMD]
# IP address of the management node (this system)
ID=2
HostName=192.168.131.26
```

```
# Section for the storage nodes
[NDBD]
# IP address of the first storage node
HostName=192.168.131.77
```

```
DataDir= /var/lib/mysql-cluster

[NDBD]
# IP address of the second storage node
HostName=192.168.131.101
DataDir=/var/lib/mysql-cluster

# one [mysqld] per storage node
[mysqld]
[mysqld]
[mysqld]
[mysqld]
[mysqld]
[mysqld]
[mysqld]
:wq
```

以下在 mysql API 上操作（这里，我设定了7个API，以后可以随时加入）

Mysqld API 的配置文件:

```
Vi /etc/my.cnf
[root@ndb1 ~]# cat /etc/my.cnf
[mysqld]
ndbcluster
ndb-connectstring = "host=192.168.131.164, host=192.168.131.26"

[ndb_mgm]
connect-string = "host=192.168.131.164, host=192.168.131.26"

[ndbd]
connect-string = "host=192.168.131.164, host=192.168.131.26"
:wq
```

分别启动 ndb_mgmd/ndbd/mysqld

164/26:

```
ndb_mgmd -f /var/lib/mysql-cluster/config.ini
```

77/101:

```
Ndbd --initial
```

164/26/77/101:

```
/etc/rc.d/init.d/mysql start
```

在管理节点 ndb1(164)和 ndb2(26)上查看各节点的情况:

```
[root@ndb1 ~]# ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> show
Connected to Management Server at: 192.168.131.164:1186
Cluster Configuration
-----
[ndbd(NDB)] 2 node(s)
id=3    @192.168.131.77  (Version: 5.0.67, Nodegroup: 0, Master)
id=4    @192.168.131.101 (Version: 5.0.67, Nodegroup: 0)

[ndb_mgmd(MGM)] 2 node(s)
id=1    @192.168.131.164 (Version: 5.0.67)
id=2    @192.168.131.26  (Version: 5.0.67)

[mysqld(API)] 7 node(s)
id=5    @192.168.131.101 (Version: 5.0.67)
id=6    @192.168.131.26  (Version: 5.0.67)
id=7    @192.168.131.164 (Version: 5.0.67)
id=8    @192.168.131.77  (Version: 5.0.67)
id=9 (not connected, accepting connect from any host)
id=10 (not connected, accepting connect from any host)
id=11 (not connected, accepting connect from any host)

ndb_mgm>
```

以上说明一切正常。

将服务增加到开机启动服务项中：

164/26:

```
echo 'ndb_mgmd -f /var/lib/mysql-cluster/config.ini' > /etc/rc.d/init.d/ndb_mgmd
chmod 755 /etc/rc.d/init.d/ndb_mgmd
```

77/101:

```
Echo 'ndbd' > /etc/rc.d/init.d/ndbd
Chmod 755 /etc/rc.d/init.d/ndbd
Chkconfig --level 2345 ndbd on
```

OK，至此 mysql cluster 配置完成。

强调：

- 1) 由于数据放在内存中，需要在 ndb 节点上加大内存的数量。按照 1: 1.1 的比例，如果数据量达到 3.6GB，需要 4GB 的内存。
- 2) 由于 NDB 和 mysqld (API) 都很耗费内存，所以建议将 NDB 放在 164 和 26 上。可能启动的时候会有警告，但是没关系的。

查看数据和内存情况:

77:

```
[root@sql2 ~]# top
top - 16:39:36 up 1:59, 1 user, load average: 1.37, 0.76, 0.60
Tasks: 80 total, 2 running, 78 sleeping, 0 stopped, 0 zombie
Cpu(s): 4.0%us, 4.0%sy, 0.0%ni, 87.3%id, 2.9%wa, 0.2%hi, 1.5%si, 0.0%st
Mem: 2075600k total, 2005868k used, 69732k free, 68256k buffers
Swap: 2031608k total, 0k used, 2031608k free, 1400812k cached

PID USER PR NI VIRT RES SHR S %CPU %MEM TIME+ COMMAND
2306 mysql 25 0 119m 15m 3952 S 22 0.8 10:20.94 mysqld
23791 root 15 0 1587m 484m 31m R 20 23.9 9:34.97 ndbd
```

由于77只有2GB的内存,而在config.ini中,把1.2GB的内存分配给了NDB,所以,加上mysqld用掉的,2GB的内存似乎已经所剩无几了。

查看77上的数据大小:

```
[root@sql2 ~]# cd /var/lib/mysql-cluster/ndb_4_fs/
[root@sql2 ndb_4_fs]# du -lh
```

1.3GB

连接 API 创建数据库:

由于上面4台都做为mysqld的API,所以创建数据库的时候,都需要创建一遍。

以下操作在4台API上都需要操作:

```
# Mysql -uroot -pxxxxxxxxxxxxxx -A
Mysql> create database testdatabase;
Mysql> grant all on *.testdatabase to root@'192.168.131.%' identified by
'xxxxxxxxxxxxxxxx';
Mysql> flush privileges;
Mysql> create table test(int (1));
Mysql> insert into test(1);
Mysql> quit;
```

以上做完以后,可以通过任意一台API上创建表,并写数据到表中,其他数据库都会同步写入。

分别连接每台服务器进行检查:

```
# Mysql -uroot -pxxxxxxxxxxxxxx -A
Mysql> use testdatabase;
Mysql> select * from test;
如果输出结果完全相同,表明mysql cluster已经可以正常工作了。
```

在2台 API 上设置 LVS

Mysql cluster 做好以后，数据库分别建立同名的数据库以后，权限分配好，然后只要在一台上写入数据，其他的 NDB 就存储了相同的数据。

用程序连接任意一台 API 写数据，如果程序中未设置 API 的选择和判断，只使用了其中一个 API，一旦 API 当机，则无法写入数据，必须修改程序。即便做了 API 的判断和选择，因为没有实现负载均衡，服务器的性能没有充分利用。高可用性也没有达到目标。所以，我们现在在2台 API 之间做 LVS。

LVS 采用 ultramonkey (<http://www.ultramonkey.org>)

首先在 NDB1 (164) 和 NDB2 (26) 上下载 heartbeat 的软件包：

下载所有的 rpm 包：

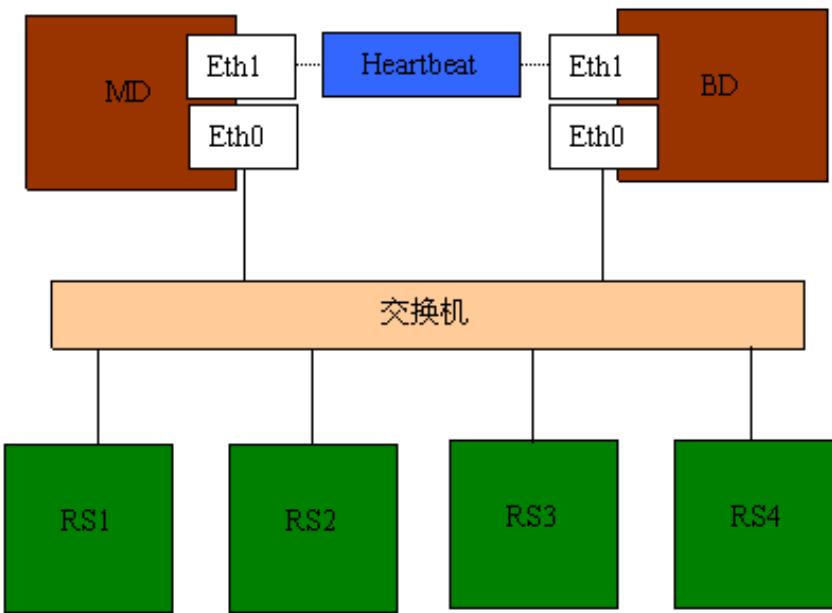

```
Cd /usr/local/src  
Mkdir heartbeat  
Cd heartbeat  
#Wget xxx.xxx.rpm
```

我下载了如下的软件包：

```
[root@ndb1 heartbeat]# ls -lh *.rpm | awk '{print $9}';  
arptables-noarp-addr-0.99.2-1.rh.el.um.1.noarch.rpm  
heartbeat-1.2.3.cvs.20050927-1.rh.el.um.4.i386.rpm  
heartbeat-ldirectord-1.2.3.cvs.20050927-1.rh.el.um.4.i386.rpm  
heartbeat-pils-1.2.3.cvs.20050927-1.rh.el.um.4.i386.rpm  
heartbeat-stonith-1.2.3.cvs.20050927-1.rh.el.um.4.i386.rpm  
ipvsadm-1.21-1.rh.el.1.um.1.i386.rpm  
libnet-1.1.2.1-1.rh.el.um.1.i386.rpm  
perl-Authen-SASL-2.08-1.rh.el.um.1.noarch.rpm  
perl-Convert-ASN1-0.18-1.rh.el.um.1.noarch.rpm  
perl-IIO-Socket-SSL-0.96-1.rh.el.um.1.noarch.rpm  
perl-ldap-0.3202-1.rh.el.um.1.noarch.rpm  
perl-Mail-IMAPClient-2.2.9-1.rh.el.um.1.noarch.rpm  
perl-Net-SSLeay-1.25-1.rh.el.um.1.i386.rpm  
perl-Parse-RecDescent-1.94-1.el5.rf.noarch.rpm  
perl-Parse-RecDescent-1.94-1.rh.el.um.1.noarch.rpm  
perl-XML-NamespaceSupport-1.08-1.rh.el.um.1.noarch.rpm  
perl-XML-SAX-0.12-1.rh.el.um.1.noarch.rpm  
[root@ndb1 heartbeat]#
```

Heartbeat 中包含以下几部分：

- 1) Master Director (分发器) -- MD
- 2) Backup Director (备份分发器) -- BD
- 3) Real server (真实服务器，可以有2个以上) -- RS

IP 设置并确认:

MD:

Eth0:192.168.131.164/24/GW:192.168.131.1

Eth1:10.9.30.1/24

MD:

Eth0:192.168.131.26/24/GW:192.168.131.1

Eth1:10.9.30.2

VIP:192.168.131.105/24/GW:192.168.131.1 -- 用户访问的统一虚拟 IP

RS1:192.168.131.101/24/GW:192.168.131.1

RS2:192.168.131.77/24/GW:192.168.131.1

...

等等

以下操作在所有服务器上执行:

主机名确认:

分别执行:

#uname -a

主机名对应表中所列。

在 MD 和 BD 修改 IP 转发:

#vi modprobe.sh

modprobe ip_vs_dh

modprobe ip_vs_ftp

modprobe ip_vs

```
modprobe ip_vs_lblc
modprobe ip_vs_lblcr
modprobe ip_vs_lc
modprobe ip_vs_nq
modprobe ip_vs_rr
modprobe ip_vs_sed
modprobe ip_vs_sh
modprobe ip_vs_wlc
modprobe ip_vs_wrr
:wq

#chmod 755 modprobe.sh

# sh modprobe.sh

# vi /etc/modules

ip_vs_dh
ip_vs_ftp
ip_vs
ip_vs_lblc
ip_vs_lblcr
ip_vs_lc
ip_vs_nq
ip_vs_rr
ip_vs_sed
ip_vs_sh
ip_vs_wlc
ip_vs_wrr
:wq
```

```
#Vi
net.ipv4.ip_forward = 0
改为:
net.ipv4.ip_forward = 1
```

使修改生效：

```
/sbin/sysctl -p
```

在 MD 和 BD 上安装 heartbeat 软件包

```
#Rpm -Uvh perl-xx-xx-xx.rpm  
#Yum install heartbeat  
#Rpm -Uvh arptables-noarp-addr-0.99.2-1.rh.el.um.1.noarch.rpm  
#rpm -Uvh perl-Mail-POP3Client-2.17-1.el5.centos.noarch.rpm
```

缺少 perl 包，就使用 yum install perl-xx-xx

```
#Perl -CPAN -e shell
```

这样安装的 perl 包不知道为何不好使？奇怪

这里 VIP 实际上是绑定在2台 director 上。所以 director 之间需要做心跳处理。心跳线使用 eth1 口，用交叉线连接起来。

交叉线的一端：

另外一端：

这样可以避免影响其他服务器。

配置 heartbeat

Heartbeat 有3个配置文件：

Ha.cf

Authkeys

Haresources

ldirectord 进程的配置文件

Ldirectord.cf

一共需要配置4个配置文件。

```
#vi ha.cf

logfacility local0

bcast      eth1

mcast eth1 225.0.0.1 694 1 0

auto_failback off

node       ndb1

node       ndb2

respawn hacluster /usr/lib/heartbeat/ipfail

apiauth ipfail gid=haclient uid=hacluster
```

:wq

```
# vi authkeys

auth 3

3 md5 514a49f83820e34c877ff48770e48ea7
```

:wq

```
# vi haresources

ndb1      \
ldirectord::ldirectord.cf \
LVSSyncDaemonSwap::master \
```

IPAddr2::192.168.131.105/24/eth0/192.168.131.255

Ndb2上需要将主机名更改一下。

:wq

设置属性并使 heartbeat 开机启动

```
# chmod 600 /etc/ha.d/authkeys  
  
#/sbin/chkconfig --level 2345 heartbeat on  
  
#/sbin/chkconfig --del ldirectord
```

启动 heartbeat:

```
/etc/init.d/ldirectord stop  
  
/etc/init.d/heartbeat start
```

在 MD 和 BD 上检查 VIP 是否生效:

```
ip addr sh eth0  
  
[root@ndb1 ha.d]# ip addr sh eth0  
  
2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast qlen 1000  
    link/ether 00:30:48:28:c6:85 brd ff:ff:ff:ff:ff:ff  
    inet 192.168.131.164/24 brd 192.168.131.255 scope global eth0  
        inet 192.168.131.105/24 brd 192.168.131.255 scope global secondary eth0  
            inet6 fe80::230:48ff:fe28:c685/64 scope link  
                valid_lft forever preferred_lft forever  
  
[root@ndb1 ha.d]#
```

```
[root@ndb2 ~]# ip addr sh eth0
```

```
2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast qlen 1000
    link/ether 00:30:48:28:c4:af brd ff:ff:ff:ff:ff:ff
    inet 192.168.131.26/24 brd 192.168.131.255 scope global eth0
        inet6 fe80::230:48ff:fe28:c4af/64 scope link
            valid_lft forever preferred_lft forever
```

```
[root@ndb2 ~]#
```

现在在 MD (164) 上已经生效了。

检查 ldirectord 进程

```
[root@ndb1 ha.d]# /usr/sbin/ldirectord ldirectord.cf status
ldirectord for /etc/ha.d/ldirectord.cf is running with pid: 5596
[root@ndb1 ha.d]#
[root@ndb2 ~]# /usr/sbin/ldirectord ldirectord.cf status
ldirectord is stopped for /etc/ha.d/ldirectord.cf
[root@ndb2 ~]#
```

VIP 生效的 director 应该是 running 状态, standby 应该是 stop 状态。

利用 ipvs 检查包转发是否生效

```
[root@ndb1 ha.d]# /sbin/ipvsadm -L -n
IP Virtual Server version 1.2.1 (size=4096)
Prot LocalAddress:Port Scheduler Flags
    -> RemoteAddress:Port           Forward Weight ActiveConn InActConn
TCP   192.168.131.105:3306 wrr
```

```
-> 192.168.131.77:3306      Route 1 3 3034
```

```
-> 192.168.131.101:3306     Route 1 3 3038
```

```
[root@ndb1 ha.d]#
```

```
[root@ndb2 ~]# /sbin/ipvsadm -L -n
```

```
IP Virtual Server version 1.2.1 (size=4096)
```

```
Prot LocalAddress:Port Scheduler Flags
```

```
-> RemoteAddress:Port      Forward Weight ActiveConn InActConn
```

```
[root@ndb2 ~]#
```

在 MB 上已经生效了。

在 MD 和 BD 上检查 LVSSyncDaemonSwap 的状态:

```
[root@ndb1 ha.d]# /etc/ha.d/resource.d/LVSSyncDaemonSwap master status
```

```
master running
```

```
(ipvs_syncmaster pid: 5689)
```

```
[root@ndb1 ha.d]#
```

```
[root@ndb2 ~]# /etc/ha.d/resource.d/LVSSyncDaemonSwap master status
```

```
master stopped
```

```
(ipvs_syncbackup pid: 5493)
```

```
[root@ndb2 ~]#
```

同样， standby 的处于 stopped 状态。

以下在 RS 服务器上执行：

ARP 转发限制

MD 或者 BD 采用 ARP 欺骗将 ARP 包转发给下面的 realserver。为了转发成功，需要做 ARP 限制。

```
#/etc/init.d/arptables_jf stop  
  
#/usr/sbin/arptables-noarp-addr 192.168.6.240 start  
  
#/etc/init.d/arptables_jf save  
  
#/sbin/chkconfig --level 2345 arptables_jf on  
  
#/etc/init.d/arptables_jf start
```

查看限制链表

```
[root@sql12 mysql-cluster]# /sbin/arptables -L -v -n  
  
Chain IN (policy ACCEPT 29243 packets, 819K bytes)  
  
      pkts bytes target     in      out      source-ip           destination-ip  
      source-hw        destination-hw    hlen     op      hrd      pro  
  
          54   1512  DROP      *       *      0.0.0.0/0          192.168.131.105  
00/00          00/00          any    0000/0000  0000/0000  0000/0000  
  
  
Chain OUT (policy ACCEPT 3931 packets, 110K bytes)  
  
      pkts bytes target     in      out      source-ip           destination-ip  
      source-hw        destination-hw    hlen     op      hrd      pro  
  
          0     0  mangle     *      eth0    192.168.131.105      0.0.0.0/0  
00/00          00/00          any    0000/0000  0000/0000  0000/0000  
--mangle-ip-s 192.168.131.101
```

Chain FORWARD (policy ACCEPT 0 packets, 0 bytes)

pkts	bytes	target	in	out	source-ip	destination-ip		
source-hw			destination-hw		hlen	op	hrd	pro

[root@sql2 mysql-cluster]#

[root@sql1 ~]# /sbin/arptables -L -v -n

Chain IN (policy ACCEPT 29375 packets, 823K bytes)

pkts	bytes	target	in	out	source-ip	destination-ip		
source-hw			destination-hw		hlen	op	hrd	pro
54	1512	DROP	*	*	0.0.0.0/0	192.168.131.105		
00/00			00/00		any	0000/0000	0000/0000	0000/0000

Chain OUT (policy ACCEPT 3903 packets, 109K bytes)

pkts	bytes	target	in	out	source-ip	destination-ip		
source-hw			destination-hw		hlen	op	hrd	pro
0	0	mangle	*	eth0	192.168.131.105	0.0.0.0/0		
00/00			00/00		any	0000/0000	0000/0000	0000/0000

--mangle-ip-s 192.168.131.77

Chain FORWARD (policy ACCEPT 0 packets, 0 bytes)

pkts	bytes	target	in	out	source-ip	destination-ip		
source-hw			destination-hw		hlen	op	hrd	pro

[root@sql1 ~]#

这样，由 MD 或者 BD 转发过来的 ARP 包就被链表控制了。

设置如何接收 ARP 包

以下在所有 RS 上执行

```
# cp /etc/sysconfig/network-scripts/ifcfg-lo
/etc/sysconfig/network-scripts/ifcfg-lo:0
#Vi /etc/sysconfig/network-scripts/ifcfg-lo\:0
DEVICE=lo:0
IPADDR=192.168.131.105
NETMASK=255.255.255.255
NETWORK=192.168.131.0
BROADCAST=192.168.131.255
ONBOOT=yes
NAME=loopback
:wq
#/sbin/ifup lo
```

查看 lo:0

```
[root@sql1 ~]# ip addr sh lo
1: lo: <LOOPBACK,UP,LOWER_UP> mtu 16436 qdisc noqueue
    link/loopback 00:00:00:00:00:00 brd 00:00:00:00:00:00
        inet 127.0.0.1/8 scope host lo
          inet 192.168.131.105/32 brd 192.168.131.255 scope global lo:0
```

```
inet6 ::1/128 scope host  
    valid_lft forever preferred_lft forever  
[root@sql1 ~]#
```

```
[root@sql2 mysql-cluster]# ip addr sh lo  
  
1: lo: <LOOPBACK,UP,LOWER_UP> mtu 16436 qdisc noqueue  
    link/loopback 00:00:00:00:00:00 brd 00:00:00:00:00:00  
    inet 127.0.0.1/8 scope host lo  
        inet 192.168.131.105/32 brd 192.168.131.255 scope global lo:0  
        inet6 ::1/128 scope host  
            valid_lft forever preferred_lft forever  
[root@sql2 mysql-cluster]#
```

重新启动服务器

以下在所有服务器上执行（请确认 ip，服务器上没有 running 任何正在使用的服务）

```
reboot
```

启动 mysql cluster:

顺序：

```
ndb_mgmd -- 164/26
```

```
Ndbd -- 101/77
```

```
Mysqld -- 所有
```

检查服务是否正常

以下在 ndb 上执行

```
#ndb_mgm
```

```
[root@ndb1 ha.d]# ndb_mgm
```

```
-- NDB Cluster -- Management Client --
```

```
ndb_mgm> show
```

```
Connected to Management Server at: 192.168.131.164:1186
```

```
Cluster Configuration
```

```
-----
```

```
[ndbd(NDB)] 2 node(s)
```

```
id=3    @192.168.131.77  (Version: 5.0.67, Nodegroup: 0, Master)
```

```
id=4    @192.168.131.101  (Version: 5.0.67, Nodegroup: 0)
```

```
[ndb_mgmd(MGM)] 2 node(s)
```

```

```

```
id=9 (not connected, accepting connect from any host)
```

```
id=10 (not connected, accepting connect from any host)
```

id=11 (not connected, accepting connect from any host)

ndb_mgm>

一切正常。

检查 heartbeat 是否正常:

关闭 BD, 在 MD 上查看日志:

```
[root@ndb1 ha.d]# tail -f /var/log/messages
```

```
Dec 17 19:42:21 ndb1 heartbeat: [5462]: info: Received shutdown notice from 'ndb2'.
```

```

Dec 17 19:42:23 ndb1 IPAddr2[7291]: INFO: Running OK
```

如果没有出现异常，表明一切正常。

破坏性试验

1) 检查 ndbd

关闭任意一台 ndbd 的进程，在 ndb_mgm 上查看是否失去连接。

如果失去连接，表示已经识别出来。

此时在数据库表中增加内容之后启动刚刚关闭的 ndbd，检查新写入的数据是否已经被同步过来。如果同步过来，一切正常。

2) 检查 heartbeat

关闭 MD, 检查 BD 的反应:

```
[root@ndb2 ~]# tail -f /var/log/messages

Dec 17 19:47:22 ndb2 harc[6862]: info: Running /etc/ha.d/rc.d/status status

Dec 17 19:48:18 ndb2 kernel: IPVS: ip_vs_wrr_schedule(): no available servers
```

如果没有错误，表明 heartbeat 已经切换。

此时再次插入数据验证，如果还可以继续写入，表明配置完全成功。

Mysql cluster 的测试报告：

在192.168.8.48上部署测试脚本，让这台服务器表示一个客户端请求读写数据库。

测试脚本1：

```
[root@localhost mysql-cluster]# cat /data/pay.kingsoft.com/wwwroot/test.php
<?php
$link = mysql_connect('192.168.131.105', 'ldirector', 'xxxxxxxxxx');
mysql_select_db('kingsoft', $link);

$sql           =           "insert           into
`preference`(`id`, `preferenceSerialNumber`, `username`, `preferenceTypeId`, `isExp
ired`, `isUsed`, `preferenceUsername`, `equalMoney`, `genDatetime`, `useDatetime`, `g
rantDatetime`, `expriedDatetime`)
values
( NULL, '514a49f83820e34c877ff48770e48ea7', 'liujun', '2', '1', '1', 'kingsoft', '512.
23', '2008-12-03', '2008-12-03', '2008-12-03', '2008-12-03')";
for($i = 0;$i < 100 ;$i++) {
    mysql_query($sql);
```

```
}
```

```
mysql_close($link);
```

```
?>
```

测试脚本2:

```
[root@localhost mysql-cluster]# cat test.sh
```

```
#!/bin/sh
```

```
i=0;
```

```
j=0;
```

```
while [ $i -lt 1000 ]
```

```
do
```

```
wget -q http://pay.kingsoft.sug/test.php;
```

```
i=`expr $i + 1`;
```

```
done
```

```
sleep 2;
```

```
find . -name "test.php.*" | xargs rm -rf ;
```

```
while [ $j -lt 1000 ]
```

```
do
```

```
mysql -uldirector -pxxxxxxxxxxx -h192.168.131.105 -e "use kingsoft;"
```

```
insert into preference (preferenceSerialNumber, username, preferenceTypeId, preferenceUsername, equalMoney, genDatetime, useDatetime, grantDatetime, expriedDatetime)
values ('514a49f83820e34c877ff48770e48ea7', 'liujun2', '3', 'liujun33333', '33.8', '2008-12-23 7:05:00', '2008-12-23 7:15:00', '2008-12-23 7:25:00', '2008-12-23 7:35:00');

j=`expr $j + 1`;

done

sleep 3;

server=`mysql -uldirector -pxxxxxxxxxx -h192.168.131.105 -e "use kingsoft;select count(*) from preference"`;

datetime=`date +%T`;

echo $datetime"-----"$server >> /tmp/mysql-cluster/mysql.log;

[root@localhost mysql-cluster]#
```

测试时间：

在192.168.8.48的 cron 中添加：

```
[root@localhost mysql-cluster]# crontab -e

*/3 * * * * sh /tmp/mysql-cluster/test.sh > /dev/null 2>&1

[root@localhost mysql-cluster]#
```

连续运行24小时。

测试结果：

```
#Cat mysql.log

14:31:54-----count (*) 21022

14:35:00-----count (*) 42634

14:37:57-----count (*) 63608

14:59:29-----count (*) 209921

15:02:03-----count (*) 231380

15:03:51-----count (*) 252231

15:05:12-----count (*) 269825

15:05:33-----count (*) 271824

15:08:05-----count (*) 291141

15:10:59-----count (*) 311836

15:14:00-----count (*) 332951

15:16:57-----count (*) 353841

15:19:59-----count (*) 374977

15:23:03-----count (*) 396181

15:26:01-----count (*) 417064

15:29:01-----count (*) 438098
```

```
15:32:03-----count (*) 459191
15:35:05-----count (*) 480229
15:38:05-----count (*) 501222
15:41:02-----count (*) 521868
15:43:59-----count (*) 542721
15:47:02-----count (*) 563841
16:00:32-----count (*) 698215
18:50:49-----count (*) 2105513
19:09:01-----count (*) 2105513
19:26:13-----count (*) 2105513
19:27:28-----count (*) 2105513
[root@localhost mysql-cluster]#
```

测试结果分析：

- 1) 当逐渐增加负载，数据库的负载并不大，CPU 占用率为30%，而内存则由600MB 逐渐升至2GB，最终达到极限。
- 2) 数据并发量大，并未引起数据库的异常，表明负载均衡已经解决了单台服务器负载太大的引起的瓶颈。
- 3) 由于内存有限（2GB），当表中数据达到一定量以后，会出现表满现象。这种情况可以通过增加内存来解决。
- 4) mysql cluster 可以实现高可用性、负载均衡，并且通过优化参数使其进一步稳定服务。
- 5) 可以采用6.3版本的mysql cluster，来减小 NDBD 内存用量。
- 6) Mysql cluster 的性能一般，比 mysql replication 慢。

需要注意的问题：

- 1) 当 ndbd 第一次启动的时候或者 config.ini 更改的时候，需要加--initial 参数进行初始化。
- 2) 尽可能的不要人工干预系统，出现问题需要谨慎对待。

以下是一个外国人写的注意事项和优化：

1. Broken up into three parts. The MySQL servers sit separate from the NDB Storage Engine, which are storage nodes (NDB nodes). The third part is called a management server. The management server, oddly enough, isn't required once the cluster is up and running unless you want to add another storage node.
2. Memory based storage engine. If you're not using 5.1+ then you must have enough RAM in each storage node to store the data set. This means that if you have four machines with 4GB of RAM each you can store 8GB of data (16GB of total storage divided by two for two copies of the data set).
3. Storage nodes are static and pre-allocate resources on startup.
4. Supports transactions and row level locking.
5. Should be noted this is a storage engine so you can't create MyISAM or InnoDB tables inside of a cluster.
6. Uses fixed sized records. This means if you have a varchar(255) and put a single byte into it that field is still using 255 bytes.
7. No foreign key constraint support.
8. Replication across nodes is synchronous across nodes. I assume this means that an INSERT happens once all of the nodes have completed the INSERT. This is different than regular replication which is asynchronous and introduces race conditions.
9. Tables are divided into fragments (one fragment for each storage node). Each storage node is responsible for each fragment. Each fragment also has a secondary

fragment, which is a copy of another node's primary fragment. This data distribution happens automatically.

10. NDB takes your primary key, creates a hash and then converts that to a fragment. So you'll have various rows on each different storage node.

11. A node group is a set of nodes that share the same fragment information. If you lose an entire node group you've lost half of the table and the cluster will not continue to operate. However, if one node in a node group fails there will still be enough data to keep the cluster up and running.

12. If a node fails and its secondary counterpart takes over it will, essentially, have to perform the job of two nodes. Until a node has fully recovered it will not rejoin the cluster.

13. Backups are hot and non-locking. Each node writes its own set of backup files. No support for incremental backups.

14. Because it's memory based you could lose data on a system crash (as you might have transactions sitting in RAM when a crash occurs). The COMMIT command does not write changes to disk meaning that you could have data sitting in memory that's not on disk when a node crashes. This means the odd truth is that MySQL Clusters support synchronous replication, but are not atomic.

15. NDB nodes will checkpoint data to disk (data + logs), which are used for system recovery. They write two logs, the UNDO and REDO logs.

16. They recommend using TRUNCATE to delete all rows from a table.

17. Modification operations are distributed to both the primary and secondary fragments (obviously).

18. NDB will run on 64-bit machines. They recommend Dual CPU 64-bit machines. NDB is threaded. Application nodes (MySQL servers) can be whatever.

19. SCI offers 30–100% better performance over gigabit.

20. They actually recommend avoiding joins and to denormalize your schemas. Are you kidding me? He actually said “Performance for joins sucks.”

Overall, I’m underwhelmed by MySQL Clustering. You’re limited in storage with the RAM and you can’t optimize your schemas due to fixed field sizes. And any RDBMS “solution” that recommends you denormalize puts me off.

That being said the actual technology is pretty interesting and I suspect that in a few years we’ll see the clustering features in MySQL come into their own. As of now I suspect few people would be able to justify the sacrifices for the gains clustering allows.
